1.0 INTRODUCTION

PRC Environmental Management, Inc. (PRC), was tasked by the U.S. Environmental Protection Agency (U.S. EPA) to conduct expanded site inspections (ESI) in Region 5 under Contract No. 68-W8-0084, Work Assignment No. 36-5JZZ.

The primary objective of an ESI is to determine whether a site has the potential to be placed on the National Priorities List (NPL). The NPL identifies sites where releases or threatened releases of hazardous substances pose a serious enough risk to public health or the environment to warrant further investigation and possible remediation under the Comprehensive Environmental Response, Compensation, and Liability Act of 1980 (CERCLA), and the Superfund Amendments and Reauthorization Act of 1986 (SARA).

Information gathered during the ESI is used to generate a preliminary Hazard Ranking System (HRS) score. The HRS is the primary criterion U.S. EPA uses to determine whether a site should be placed on the NPL (Federal Register 1990). ESIs are generally conducted at sites where additional environmental sampling or monitoring well installation is necessary to fulfill HRS documentation requirements, and to address site issues not adequately resolved in previous investigations.

Specifically, the objectives of the ESI are as follows:

- To investigate and document critical hypotheses or assumptions not completely tested during previous investigations
- To collect samples to attribute hazardous substances to site operations
- To collect samples to establish representative background levels
- To collect any other missing HRS data
- To document current site conditions
- To assess the need for emergency response actions

After the ESI report is finalized, U.S. EPA, in consultation with state authorities, will determine whether the site should undergo further investigation or should be designated "no further remedial

action planned (NFRAP). The NFRAP designation means that no additional investigations will be conducted based on information available at the time of the NFRAP designation. However, if new site information is brought to U.S. EPA's attention, the site may be reevaluated. For sites warranting further investigation under CERCLA and SARA authority, an HRS scoring package will be prepared using data collected during the ESI and previous investigations. Preparation of an HRS package may result in NPL listing of the site.

This report documents the results of an ESI conducted at the Systech Liquid Treatment Corporation (Systech) site in Franklin, Warren County, Ohio. PRC gathered and reviewed information from the Ohio Environmental Protection Agency (OEPA) and from U.S. EPA Region 5 CERCLA files. PRC performed a reconnaissance inspection of the Systech site on April 22, 1993. The inspection included an interview with the site representative and a walk-through inspection of the site. PRC subsequently prepared an ESI site-specific implementation plan (SSIP) and submitted the plan to U.S. EPA for approval. U.S. EPA approved the SSIP on June 18, 1993. PRC collected 11 groundwater, 2 sediment, and 5 soil samples at the Systech site during the ESI, which was conducted on June 21 and June 25, 1993.

2.0 SITE BACKGROUND

This section describes the Systech site, and summarizes site history, waste handling practices, regulatory and release history, and previous investigations.

2.1 SITE DESCRIPTION

The Systech site is an inactive waste treatment facility located in Franklin, Warren County, Ohio (see Figure 1). The site is located in the former City of Franklin wastewater treatment plant, on a 2.3-acre property currently owned by the Miami Conservancy District (MCD). Downtown Franklin is about 1 mile northeast of the site. The Great Miami River is about 2,500 feet north of the site (U.S. Geological Survey [USGS] 1965a).

The site is surrounded by a chain-link fence that is topped with barbed wire. Locked gates are located at several locations around the site perimeter (PRC 1993b). Clear Creek is about 100 feet north of the northern site fence. An overgrown gravel drive and wooded area are between the site and Clear Creek. The gravel drive also extends around the eastern side of the site; a wooded area is beyond the gravel drive. The site is bordered by Ohio State Route 73 on the south and Baxter Road on the west (see Figure 2).

The population of Franklin is about 11,000; about 48,753 people live within a four-mile radius of the site (U.S. Department of Commerce 1991; Frost Associates 1994). Land use in the surrounding area is mixed residential, industrial, commercial, and agricultural. MCD's current wastewater treatment plant for the City of Franklin occupies much of the area north of the site, between Clear Creek and the Great Miami River. Some of the MCD property is used for drying and experimental spray application of treated sewage sludge. Residential housing and a cornfield are northeast of the site, north of Clear Creek. The nearest off-site residences are located directly across Clear Creek from the eastern part of the site. IKO Productions, a roofing manufacturer, is located south of the site, in an industrial area south of State Route 73 (PRC 1993b).

The average daily temperature in Franklin is 62°. The average total annual precipitation is 37 inches; net precipitation is in the 15-inch to 30-inch range (U.S. Department of Agriculture [USDA] 1973;

SITE FEATURES
PRC ENVIRONMENTAL MANAGEMENT, INC.

Federal Register 1990). The maximum 2-year, 24-hour rainfall is about 2.75 inches (National Oceanic and Atmospheric Administration [NOAA] 1992).

Subsurface materials in the site vicinity consist of unconsolidated glacial drift overlying shale bedrock. The site is located on the southeast margin of the Great Miami River buried valley aquifer. This buried valley contains thick sand and gravel deposits that form a major aquifer system in southwest Ohio (Ohio Department of Natural Resources [ODNR] 1960). About 26,864 people use drinking water obtained from this aquifer at locations within a 4-mile radius of the Systech site (ODNR 1954-1983; City of Franklin 1992; PRC 1992c; 1992d; 1993a; 1994a; 1994b; Frost Associates 1994). Some of these people are served by groundwater-based municipal systems, while others use private wells. The nearest municipal wells are the City of Franklin wells, which serve a population of about 11,500 (PRC 1992a; 1993a). The wells are located along the Great Miami River. Three of these wells are located between 0.5 and 1 mile away from the Systech site; the fourth well is about 1.5 miles away (City of Franklin 1992; PRC 1992a; 1993b). The nearest private well is reportedly located about 1 mile west of the site, west of the Great Miami River (Ecology & Environment [E&E] 1987; Geraghty and Miller Engineers, Inc. [G&M] 1989).

Surface runoff from the site flows into Clear Creek, either directly or by way of drainage ditches located along the southern and western site boundaries. Clear Creek converges with the Great Miami River about 0.8 mile downstream (west) from the site (USGS 1965a). Surface water in the area is not used as a source of drinking water but is used for fishing (PRC 1992b). Runoff also tends to pond in several subgrade structures at the site (see Section 3.1) that were originally part of the treatment plant operations (PRC 1993b).

2.2 SITE OPERATIONS

From the 1930s to 1972, the City of Franklin operated a municipal wastewater treatment plant on the site property. When the new wastewater treatment plant (north of the site) was constructed in 1972, the city deeded the original plant and the new facility to the MCD (E&E 1987; PRC 1993b). MCD is a regional government agency that performs a variety of functions related to water resource management and flood control in the Great Miami River Basin (PRC 1993b).

MCD leased the old treatment plant property to Systems Technology Corporation (STC). Although STC used the property for waste treatment opertions, the site is known as the Systech site due to subsequent changes in corporate structure and ownership. In 1979 STC changed its name to Systech Liquid Treatment Corporation (Systech) and became a subsidiary of a parent company named Systech Corporation. In 1982 the Systech subsidiary was purchased by Tricil, Inc., and in 1983 the corporation's name was changed to Tricil Environmental Services, Inc. However, Systech Corporation retained responsibility for the Franklin, Ohio facility (E&E 1987; PRC 1993b).

STC performed two basic operations at the site: liquid waste treatment and solvent recovery. From 1974 to 1978 STC received liquid industrial wastes including cyanide-contaminated wastes, plating wastes, acids and bases, phenol-contaminated water, oily wastes, and some food wastes. These wastes were stored in several subgrade structures (trickling filters, clarifiers, and treatment chambers) remaining on site from the former wastewater treatment plant, as well as in drums and several aboveground storage tanks. Compatible wastes were combined, neutralized, and pumped to MCD's new wastewater treatment plant for final treatment and discharge. According to available information, no wastes were disposed of on site (OEPA 1986; E&E 1987: PRC 1993b).

STC operated a solvent recovery process from 1976 to 1978 (OEPA 1986; E&E 1987; PRC 1993b). Available information indicates that a total of 694,000 gallons of waste solvents was treated on site (E&E 1987). The site applied for a permit to operate as a preincineration processing facility in 1975 (PRC 1992e). For a 3- to 5-month period (year unknown), solvents from STC were incinerated at the new wastewater treatment plant 1,500 feet north of the site (E&E 1987). As with the other liquid wastes handled on site, available information does not indicate that STC disposed of any solvent-related materials on site; however, spills and day-to-day handling may have resulted in some liquid wastes and solvent entering site soils.

Chemical spills were reported at the site as early as 1975 (Franklin Chronicle 1986). On August 23, 1975, two employees died while cleaning a tank containing cyanide-laden sludges (E&E 1987). In 1977 a reported spill of organic chemicals resulted in an investigation by MCD of potential groundwater contamination (OEPA 1986; E&E 1987).

In August 1978 an odor problem developed at the site. The problem was reportedly related to spent paint, thinner, solvents, and sludges that were drained from two 12,000-gallon storage tanks into diked areas surrounding the tanks (Franklin Chronicle 1986; OEPA 1992; PRC 1992e). However, during the ESI reconnaissance in 1993, Systech representatives indicated that the odor was caused by the solvent recovery process (PRC 1993b). The odor problem was reportedly so severe that residents 2 miles from the site complained of odors (OEPA 1986). OEPA and the Southwest Ohio Air Pollution Control Office inspected the site on August 18 and 22, 1978. However, no air sampling was performed to confirm the source or nature of the odors, and apparently STC held no air permits for the on-site operations. Therefore, the chemical compounds responsible for the odors and the concentrations potentially released to the air are unknown.

The site was closed on August 18, 1978 (Franklin Chronicle 1986). Following closure all STC equipment, buildings, and aboveground tanks were removed from the site. However, the original wastewater treatment plant structures (pump house, clarifiers, trickling filters, treatment tanks, and concrete foundations) were not removed. According to Systech representatives, buried underground storage tanks were never present at the site (PRC 1993b).

2.3 PREVIOUS INVESTIGATIONS

Due to concerns regarding potential groundwater contamination, MCD installed three groundwater monitoring wells at the site in November 1977. Groundwater samples collected from the wells in November 1977 reportedly contained the following volatile organic compounds (VOC): methanol, at a concentration of 23.3 milligrams per liter (mg/L); toluene (5.86 mg/L); methyl ethyl ketone (6.1 mg/L); xylenes (140 micrograms per liter [μg/L]); isopropanol (14.9 mg/L); and ethyl acetate (19.5 mg/L) (OEPA 1986).

MCD installed a fourth monitoring well at the site in 1979. Systech subsequently used two of the monitoring wells (W139 and W140) to extract contaminated groundwater (OEPA 1986). Systech removed about 21 million gallons of groundwater during the remediation efforts. The water was pumped to the MCD plant for treatment. In 1979 OEPA decided that Systech could cease groundwater extraction because it would have little additional benefit (E&E 1987; PRC 1993b).

In 1986 OEPA found that the laboratory results on which its 1979 decision to stop remediation had been based were no longer acceptable under 1986 standards (OEPA 1992). The City of Franklin subsequently contracted Soil and Material Engineers (SME) to determine if groundwater at the site was still contaminated and to identify the contaminant source. As part of its investigation, SME sampled the on-site monitoring wells. Table 1 lists the concentrations of contaminants detected in the groundwater samples (OEPA 1986).

TABLE 1

RESULTS OF 1986 SAMPLING EVENT

Contaminant	Monitoring Well No.	Concentration (μg/L)
Chromium	W132	128
	W139	52
Toluene	W139	16,000
Ethylbenzene	W139	7,800
Xylene	W139	2,510
Polychlorinated biphenyls(PCB) as Aroclor 1248	W132	69

In 1986, OEPA prepared a preliminary assessment (PA) of the Systech site recommending a medium priority for further investigation (OEPA 1986).

In May 1987, the U.S. EPA Field Investigation Team (FIT) conducted a screening site inspection (SSI) at the Systech site. The SSI included collection of seven groundwater samples, one residential well sample, and four soil samples. The results of the groundwater analyses indicated that groundwater at the Systech site contained the VOCs 1,1,1-trichloroethane (TCA) (at a reported concentration of 15 μg/L), vinyl chloride (29 μg/L), ethylbenzene (2,700 μg/L), and xylenes (9,400 μg/L), and the Target Analyte List (TAL) analyte arsenic (66 μg/L). The results of the soil sample analyses indicated that site soils contained significant concentrations of the VOCs 1,1,1-TCA, trichloroethene (TCE), tetrachloroethene (PCE), and the TAL analyte chromium (E&E 1987). The presence of solvents (specifically 1,1,1-TCA) in groundwater and soil samples indicated that the

groundwater contamination was related to spills occurring when waste was handled on site at Systech. However, 1,1,1-TCA was the only groundwater contaminant that was also detected in the soil samples (E&E 1987).

From 1990 to 1992, Terran Corporation (Terran) performed a hydrogeologic investigation at the Systech site, on behalf of Systech Corporation. Terran installed seven additional groundwater monitoring wells and performed quarterly groundwater sampling, as well as surface water sampling and a soil gas survey. During the investigation, the VOCs benzene, cis-1,2-dichloroethene, ethylbenzene, toluene, and vinyl chloride were detected in W139. Chromium and arsenic were also detected in several of the on-site monitoring wells (Terran 1993).

In 1989 G&M, on behalf of Systech Corporation, evaluated the Systech site for its potential to be placed on the NPL. G&M estimated a potential HRS score for the site, based on the assumption that several municipal wells in Middletown, Ohio were located within 4 miles of the Systech site. However, information gathered by PRC indicates that all of the Middletown wells are more than 4 miles away from the Systech site (City of Middletown 1993).

3.0 ESI ACTIVITIES

This section presents field observations and sampling procedures at the Systech site. Individual subsections address the reconnaissance and sampling inspections. Rationales for specific ESI activities are also provided. The ESI was conducted in accordance with the U.S. EPA-approved SSIP, dated June 16, 1993, and the U.S. EPA-approved generic quality assurance project plan (QAPjP), dated October 7, 1991. The U.S. EPA Potential Hazardous Waste Site Inspection Report (Form 2070-13) for the Systech site is provided in Appendix A. Photographs taken by PRC during the inspection activities are included in Appendix B.

3.1 SITE RECONNAISSANCE

PRC performed a reconnaissance of the Systech site on April 22, 1993. The site reconnaissance consisted of an interview with site representatives and a visual inspection of the site. The purpose of the inspection was to determine appropriate health and safety requirements for on-site sampling activities, evaluate the need for immediate removal actions, choose sampling locations, and locate and evaluate nearby targets. PRC was accompanied on the reconnaissance by two representatives of OEPA's Southwest District Office. Observations made during the inspection are presented herein. All information is based on PRC's observations unless otherwise referenced.

Upon arrival at the Systech site, PRC met with Mr. Stephen Zimmer of Systech Environmental Corporation (a subsidiary of Systech Corporation) and Mr. Paul Plummer of MCD. During the inspection Mr. Zimmer and Mr. Plummer explained the history and operations of the Systech site. Mr. Zimmer also discussed the general nature of the wastes handled at the site and waste treatment methods.

The site is surrounded by a chain-link fence that has locked gates and is topped with barbed wire (Photograph No. 1). The pump house is the only remaining building on site (Photograph No. 2). Other remaining structures include subgrade concrete pits and chambers where the trickling filters, clarifiers, and treatment tanks were formerly located (Photograph No. 3). These structures were all part of the former City of Franklin wastewater treatment plant. STC used these structures to store liquid wastes and sludges during site operations. Several concrete slabs (remnants of foundations)

a concrete loading dock from the STC solvent recovery operation also remain on site (Photograph No. 4). The outlines of several metal aboveground tanks used by STC are visible on the slabs; however, no aboveground tanks remain on site (Photograph No. 5). The trickling filters, clarifiers, treatment tanks, and loading dock areas were empty except for some rainwater that had ponded in low areas, and a few empty 55-gallon drums. About 20 55-gallon drums, apparently used to contain purge water during 1991 and 1992 sampling events, remain in the area near the former loading dock (Photograph No. 6).

Most of the site is open with few trees, except along the northern and eastern boundaries, and around the pump house. A partially-overgrown gravel drive and drum storage area are present in the western part of the site. Most of the site is covered with grass; some heavy brush is present in the eastern parts of the site. Vegetation did not appear to be abnormally stressed.

Most of the site appears to be well drained except for the subgrade structures. Most site surface runoff flows into perimeter ditches on the south and west which then flow into Clear Creek (Photograph Nos. 7 and 8). At the southwest corner of the site, the south ditch flows into the west ditch, which then continues northward and flows into Clear Creek at the northwest corner of the site (Photograph No. 9). Runoff from areas along the northern site boundary probably flows directly into Clear Creek.

One groundwater monitoring well (W-140) is located on site, within the fenced area. An additional nine groundwater monitoring wells are located at or near the site perimeter (outside of the fence), on both sides of Clear Creek. The four wells installed during the late 1970s (W132, W133, W139, and W140) are constructed of polyvinyl chloride (PVC). The wells installed during the Terran investigation (W181, W182, W183, W184, W185, and W186) are constructed of stainless steel. Background monitoring well W187, which is located about 500 feet east of the site, next to a residence on the north bank of Clear Creek, is also constructed of stainless steel.

The City of Franklin municipal wells are located north of the site along the Great Miami River. (Appendix C presents the locations of all identified municipal wells within a 4-mile radius of the Systech site). Several industrial supply wells are also located in the area.

3.2 SAMPLING LOCATIONS AND PROCEDURES

PRC collected 11 groundwater samples, 2 sediment samples, 5 soil samples, and related quality assurance/quality control (QA/QC) samples on June 21 and June 25, 1993. The sampling locations are presented in Figures 3 and 4, and are summarized in Table 2. Sampling locations and collection procedures were in accordance with the U.S. EPA-approved SSIP, generic QAPjP, and applicable portions of PRC's standard operating procedures (SOP). All samples were split with personnel from Terran (Roger McReady, Robert Croydon, and Robert Weber), who represented Systech Corporation. Mr. Plummer of MCD was also present during some of the sampling activities.

3.2.1 Monitoring Well (Groundwater) Samples

PRC collected groundwater samples from 11 monitoring wells at the Systech site. PRC collected samples from monitoring wells W132, W133, W181, W182, W183, W184, W185, W186, and background well W187 on June 21, 1993 (Photograph Nos. 10 through 22). Wells W139 and W140 have permanent, dedicated submersible pumps installed in the casings. MCD was unable to provide the equipment and personnel needed to operate the pumping systems on June 21; because of this, PRC sampled wells W139 and W140 on June 25 (Photograph Nos. 23 through 26). The purpose of collecting the groundwater samples was to confirm the results of previous sampling events, which had indicated that the Systech site had released contaminants to local groundwater.

Prior to sampling, PRC measured the depth to water in each well using an electronic water level probe. The water level data are presented in Table 3. PRC purged all wells prior to sampling. The pH, specific conductivity, and temperature of the purged water was monitored during the purging process. Purging continued until these parameters had stabilized and at least three times the volume of standing water in the well had been purged. PRC then collected groundwater samples from each well. Teflon bailers were used to purge and collect groundwater samples at all of the wells except W139 and W140. PRC purged wells W-139 and W-140 with the dedicated submersible pumps. Because the pumping apparatus rendered the well interiors inaccessible to bailers, PRC collected the groundwater samples through taps connected to access portals on the pump discharge pipes. The pump flow rate was reduced to the lowest possible rate that provided smooth, nonturbulent flow prior to sampling.

PRC transferred the VOC, seimvolatile organic compound (SVOC), pesticide, and polychlorinated biphenyl (PCB) sample fractions directly into sample containers. The sample fraction collected for metals analysis was filtered in the field using a battery-powered peristaltic pump equipped with 0.45-micron disposable filters. While purging wells W139 and W140, PRC noted gray-black discoloration and a hydrogen sulfide-like odor in the purged water. The water became less discolored as purging continued; however, at W139, the final sample retained a grayish tint and sulfide-like odor.

All bailers were decontaminated before mobilizing to the field. Several bailers also required decontamination in the field; in these cases, PRC used the same procedures used to decontaminate the bailers prior to mobilization. These procedures consisted of scrubbing the bailer inside and out with a solution of Alconox™ detergent and distilled water, followed by multiple rinses of distilled water. The bailers were then allowed to air dry and were wrapped in aluminum foil, to prevent inadvertent contamination in transit to the sample location.

Because sampling was performed on two different days, PRC prepared two sets of field QA/QC samples for the groundwater samples. A field duplicate of the sample from well W183 was collected on June 21, and a field duplicate of the sample from well W139 was collected on June 25. The purpose of these samples was to evaluate laboratory and field precision. The field duplicate samples were prepared by filling a complete extra set of sample containers at these two locations and submitting the extra set of sample containers for analysis as a distinct, separate sample.

Two field rinsate blanks (EB-1 and EB-2), one for each day of sampling, were also prepared in the field, to evaluate the effectiveness of decontamination procedures. Since all samples collected on June 21 were collected using bailers, the equipment rinsate blank for that day (EB-1) was prepared by pouring high-perfomance liquid chromatography-certified (HPLC) ultrapure water into a clean bailer, and then transferring the water to a set of sample containers. Since no bailers were used on June 25, the equipment rinsate blank for that day (EB-2) was collected by pouring the HPLC water directly into sample containers.

Two trip blank samples were prepared (VOC fractions only) to evaluate potential contamination originating during container preparation, handling, and transport. The trip blank samples accompanied each shipment of VOC sample fractions to the laboratory. Sample TB-1 accompanied

accompanied each shipment of VOC sample fractions to the laboratory. Sample TB-1 accompanied VOC fractions collected on June 21; sample TB-2 accompanied VOC fractions collected on June 25. The trip blanks were prepared by filling a set of VOC sample containers with HPLC water at the time the sample containers were initially prepared, prior to mobilization to the field. From that time forward, the trip blanks remained with the coolers in which the VOC sample fractions were stored and shipped.

3.2.2 Sediment Samples

PRC collected two sediment samples on June 21, 1993 to evaluate whether the Systech site has released contaminants to Clear Creek. The samples were collected using stainless-steel scoops. Three other samples, SD-3, SD-4, and SD-5, collected in the drainage ditches along the site boundary, were originally designated sediment samples in the SSIP. However, because the sample locations were dry at the time of sample collection, SD-3, SD-4, and SD-5 were redesignated as soil samples.

PRC collected sediment sample SD-2 to determine whether hazardous substances from the Systech site have been released to local surface waters. The sample was collected at the point where the western site drainage ditch flows into Clear Creek (Photograph Nos. 27 and 28). PRC also collected a background sediment sample, designated sample SD-1, from Clear Creek, about 500 feet upstream (east) from the Systech site (Photograph Nos. 29 and 30).

3.2.3 Soil Samples

PRC collected five soil samples at the Systech site on June 21, 1993. The purpose of the soil samples was to identify hazardous substances present on site, to identify areas of surficial soil contamination, and to determine if hazardous substances were migrating from the site toward Clear Creek by way of the perimeter drainage ditches. The number of soil samples collected was limited because most of the areas where waste treatment, storage, and handling reportedly occurred are covered by concrete or asphalt pavement. Three of the soil samples (SD-3, SD-4, and SD-5) were to have been sediment samples but were redesignated as soil samples because the sample locations were dry.

The soil samples were collected from a depth of about 0 to 6 inches below ground surface, using stainless-steel scoops. Soil sample SS-1 was collected in an unpaved area adjacent to the former loading dock and abandoned treatment tanks (Photograph Nos. 31 and 32). Sample SS-2 was collected southwest of the abandoned trickling filters (Photograph Nos. 33 and 34). Two soil samples (samples SD-3 and SD-4) were collected in the drainage ditches along the site's western and southern boundaries, to determine whether hazardous substances have migrated from the Systech site by way of surface runoff (Photograph Nos. 35 through 38). Sample SD-5 was collected outside the site fence, in the southeast site corner, to be used as a background sample (Photograph Nos. 39 and 40).

4.0 ANALYTICAL RESULTS

All samples collected during the ESI were analyzed through the U.S. EPA Contract Laboratory Program (CLP). The laboratories analyzed for U.S. EPA Target Compound List (TCL) VOCs, extractable SVOCs, pesticides, and PCBs. The samples were also analyzed for TAL inorganic substances (metals and cyanide). All data were reviewed by U.S. EPA Region 5 for compliance with the terms of the CLP. The laboratory results are summarized in Appendix D.

The concentrations of substances detected in the environmental samples were compared with background concentrations to determine which results were significant. Other factors, such as U.S. EPA contract required quantitation limits (CRQL) for TCL compounds and contract required detection limits (CRDL) for TAL analytes, and relevant QA/QC results, were also considered in evaluating the significance of the data. The significant results are presented in Tables 4 and 5.

4.1 MONITORING WELL SAMPLES

The significant results of the monitoring well sample analyses are presented in Table 4. The complete analytical results are summarized in Table D-1.

The TCL VOCs chloroethane, ethylbenzene, and xylenes were detected at significant concentrations in the sample from well W139. Ethylbenzene and xylenes have been detected in past sampling events at the Systech site. Also, various organic solvents (TCE, PCE) and associated degradation products (such as vinyl chloride) have been detected in groundwater samples during past sampling events at the Systech site. All of these substances are either known to have been treated at the Systech facility or are commonly related to wastes treated at the facility, such as solvents and paint waste (OEPA 1986; Sittig 1985; E&E 1987). Therefore, all of these substances appear to be attributable to the Systech site.

The VOC acetone was also detected in most of the groundwater samples. However, it was also detected in both field rinsate blank samples (EB-1 and EB-2) and trip blank sample TB-2. Also, acetone is a common laboratory contaminant and was detected in the laboratory blank sample associated with the samples from the Systech site. For these reasons, the presence of acetone in the

?	Analytical bias is unknown.
COMPOUND QUALIFIERS	**DEFINITION**
P	Variance between GC columns was greater than 25 percent in pesticide or Aroclor (PCB) analyses. The lower value is reported.

samples does not appear to be related to releases from the Systech site, and the acetone results were not considered significant. No other TCL compounds (VOCs, SVOCs, pesticides, or PCBs) were detected at significant concentrations in the groundwater samples.

The TAL analyte iron was detected in the samples from wells W132, W139, W140, and W182 at concentrations significantly above background. Iron is a naturally-occurring element in local groundwater; however the reported concentrations (particularly those reported in the samples from wells W139 and W140) appear higher than typical naturally-occurring levels. Iron is found in many types of metallic wastes. Several types of wastes that potentially contained metallic substances, such as plating wastes and cutting oils, are known to have been treated on site (E&E 1987). Therefore, it appears that the iron could be related to wastes treated at the Systech site.

The TAL analyte mercury was detected in the sample from well W181 at a concentration significantly above background; however, the reported concentration was relatively low (0.28 μg/L). Significant concentrations of mercury were not detected in on-site soil samples, and available information does not list mercury as a component of wastes handled at the Systech site. Mercury is present in some agricultural chemicals, and agricultural fields are located near well W181 (Sittig 1985; PRC 1993b). Therefore, the mercury detected in well W181 cannot be conclusively attributed to a source at the Systech site at this time.

The reported concentration of the TAL analyte arsenic in the groundwater sample from monitoring well W139 was significantly higher than the concentration detected in the background sample from well W187. Samples collected from well W139 during past sampling events have also contained arsenic concentrations higher than background well W187, indicating that the arsenic levels in site groundwater are above naturally-occurring levels for the area. Arsenic has also been detected in samples from well W140 and, on one occasion (June 1991), in well W181 (Terran 1993).

Because the highest arsenic concentrations have consistently been detected in or downgradient from the main treatment plant operations area, the arsenic may be originating from a source on the site property. However, available information regarding the types and constituents of wastes treated at the Systech site does not specify arsenic as a waste constituent. Significant concentrations of arsenic were not detected in on-site soil samples collected during the 1987 SSI or during the 1993 ESI, and

previous soil sampling performed at the site primarily focused on VOC contamination (E&E 1987). Some limited subsurface soil sampling performed by SME in 1986 indicated that elevated levels of heavy metals (most notably chromium) are present in site soils; however, arsenic was not reported in these results and it is unknown whether the samples were analyzed for arsenic (SME 1986). Previous studies have also suggested that the presence of heavy metals in site groundwater may be related to operations at the former wastewater treatment plant or to off-site sources; however no documentation supporting this theory was provided (Meinert 1980). In summary, although elevated concentrations of arsenic appear to be present in site groundwater, the source of the arsenic is unknown at this time.

4.2 SEDIMENT SAMPLES

The analytical results for sediment sample SD-2 were evaluated using the results for background sample SD-1. Significant concentrations of TCL compounds or TAL analytes were not detected in sample SD-2; therefore, no table of significant findings is presented for the sediment sample data. The complete analytical results for sediment samples are summarized in Table D-2.

4.3 SOIL SAMPLES

Soil samples SS-1, SS-2, SD-3, and SD-4 were evaluated using the results for background sample SD-5. The significant results of the soils analyses are presented in Table 4. The complete analytical results are summarized in Table D-3.

No VOCs were detected at significant concentrations. Significant concentrations of the SVOCs fluoranthene and benzo(a)anthracene were detected in samples SS-2 and SD-3. Sample SS-2 also contained significant concentrations of the SVOCs phenanthrene, pyrene, chrysene, benzo(b)fluoranthene (also known as 3,4-benzofluorene), benzo(k)fluoranthene, benzo(a)pyrene, indeno(1,2,3-cd)pyrene, and benzo(g,h,i)perylene, and the PCB Aroclor 1254. The pesticide compound 4,4'-DDE was detected in sample SD-4. No other TCL compounds or TAL analytes were detected at significant concentrations in the soil samples.

Most of the TCL compounds detected in the soil samples are polynuclear aromatic hydrocarbons (PAH). PAHs are sometimes present in waste oils and cutting oils, which are known to have been treated at the Systech site (Sittig 1985; E&E 1987). PCBs have also been detected on site in the past. The presence of TCL compounds in the soil samples at concentrations significantly above background confirms that site soils are a potential contaminant source.

5.0 PATHWAYS

This section discusses sources, pathways, and targets. The four pathways are groundwater migration, surface water migration, soil exposure, and air migration.

Based on the results of sampling and other information gathered during the ESI, soils at the Systech site are a contaminant source. Soil sample analytical results indicate that site soils contain elevated levels of TCL compounds. Also, groundwater contamination, that appears to be related to wastes treated at the Systech facility, is present beneath the site.

5.1 GROUNDWATER MIGRATION PATHWAY

The analytical results of groundwater samples collected from the on-site monitoring wells indicate that the Systech site has released contaminants to the local buried valley aquifer. These contaminants include the VOCs 1,1,1-TCA (detected in soil and groundwater samples during the 1987 SSI), chloroethane, toluene, and xylenes (all of which were detected in groundwater samples collected during the 1987 SSI or the 1993 ESI) (E&E 1987). Available information indicates that no continuous, confining layers separate the contaminated portion of the aquifer from portions of the aquifer used for water supplies. Therefore, all persons obtaining drinking water from wells drawing from the sand and gravel aquifer within a 4-mile radius of the Systech site are considered subject to potential contamination.

5.1.1 Geology and Soils

Subsurface materials in the Franklin, Ohio area generally consist of unconsolidated glacial deposits and modern alluvium overlying Ordovician-age shale and limestone bedrock. The present-day Great Miami River follows the course of a deeper, preglacial, buried bedrock valley trending generally from northeast to southwest. This valley is incised into the bedrock to depths of 200 feet or more in its deepest portions. The valley is filled with glacial outwash (sand and gravel) with occasional interbedded till layers (mostly clay and silt). The unconsolidated, valley-fill deposits are known as the Great Miami buried valley aquifer system.

The Systech site is located near the southeastern margin of the buried valley. Available information indicates that the valley deepens, and the unconsolidated, valley-fill deposits thicken, towards the northwest (ODNR 1954-83; 1960). In many areas within the buried aquifer system, the sand and gravel units are separated by a till layer. In some areas, the till acts as a confining layer. However, in the vicinity of the site, the continuity of the till zone is uncertain (USGS 1968). Cross-sections of the buried valley in the area, based on seismic surveys performed during the early 1970s, indicate that the till layer is not present in the site vicinity (Terran 1993). Most available well logs from the area do not indicate that any significant clay layers were encountered while drilling (ODNR 1954-83).

Subsurface deposits on site at Systech reportedly consist of sand and gravel, overlying silty clay, that in turn directly overlies shale bedrock. The total thickness of the unconsolidated deposits (sand, gravel, silt, and clay) ranges from about 25 feet in the southern part of the site to about 60 feet at Clear Creek. The sand and gravel layer and the underlying clay layer are both reportedly saturated. According to Terran, the two zones are hydraulically connected and are therefore considered part of the same aquifer system. The deposits also appear to be in hydraulic communication with Clear Creek and the Great Miami River (Terran 1988).

The depth to groundwater at the site ranges from about 8 to 20 feet, depending on location (PRC 1993b). During the 1986 PA OEPA determined that groundwater flow at the site is northwest, toward the deep part of the buried valley (OEPA 1992). Terran has also reported northwestward flow direction. During the ESI, PRC measured groundwater elevations in all accessible the monitoring wells (see Table 3). The piezometric data appeared generally consistent with data previously reported by Terran and MCD, which had been used to determine the northwestward flow direction in the sand and gravel aquifer (Terran 1988; 1993).

5.1.2 Groundwater Usage

Groundwater obtained from the Great Miami buried valley aquifer is the main source of drinking water in the area. About 26,900 people use groundwater-based municipal water supply systems or private wells that draw water from locations within a 4-mile radius of the Systech site (USGS 1959; 1965a; 1965b; 1965c; City of Franklin 1992; City of Springboro 1992; PRC 1992d; 1993a; 1994a; 1994c; Frost Associates 1994). Table 6 summarizes the population using groundwater within a 4-mile

TABLE 6

POPULATION USING GROUNDWATER FOR DRINKING WATER PURPOSES

Radius From Site (miles)	Municipal Wells	Private Wells
0-0.25	0	0
0.25-0.5	0	0
0.5-1	9,810	78
1-2	1,691	2,149
2-3	7,200	4,100
3-4	0	1,836
Total	18,701	8,163

radius of the Systech site. Most wells in the area draw water from the Great Miami buried aquifer system. Available local well logs indicate that most wells municipal and private wells drawing water from the aquifer are relatively shallow (less than 100 feet deep) and that no continuous confining layers are present within the sand and gravel deposits (ODNR 1954-83).

In general, the shale and limestone bedrock units do not yield sufficient amounts of groundwater for domestic use in upland areas. A few wells in the area draw water from the bedrock in areas adjacent to the buried valley where sufficient recharge is available (ODNR 1960; USGS 1968).

The City of Franklin municipal wells serve about 11,500 people (PRC 1993a; G&M 1989). Available well logs indicate that the Franklin wells are screened in sand and gravel deposits and are about 80 to 90 feet deep (ODNR 1954-83). The service area of the Franklin system includes the entire area within the city limits and part of the village of Chataqua, which is located about 2 miles north of downtown Franklin. The City of Franklin also supplies water to the Warren County Water Department for service to some areas just outside of the Franklin city limits (PRC 1994c). The Franklin water supply is blended. Three of the Franklin wells are located between 0.5 and 1 mile

from the Systech site and produce about 85 percent of Franklin's water supply. The balance of Franklin's water comes from a well that is about 1.5 miles miles away from the site (City of Franklin 1992; 1994; PRC 1992a; 1993b). All of the Franklin wells draw water from the sand and gravel deposits in the buried valley aquifer (ODNR 1954-83; PRC 1993a).

The City of Springboro is supplied by water from 3 municipal wells, located about 2.75 miles north to northeast of the site (in Chataqua). The wells are screened in the sand and gravel deposits and are about 105 feet deep. The Springboro wells serve 7,200 residents in and adjacent to the Springboro city limits and along Pennyroyal Road, which connects Springboro to Chataqua (City of Springboro 1992; PRC 1992c). The Springboro wells also draw water from the buried valley aquifer (ODNR 1954-83).

About 4,600 residents in Carlisle, Ohio, and nearby areas west of the Great Miami River (within four miles of the Systech site), are not served by municipal supplies (U.S. Department of Commerce 1991; PRC 1994a; 1994c) . Most of these residents use private wells (PRC 1994a; 1994c). Available information indicates that most of these wells draw water from the buried valley aquifer at depths of less than 80 feet (ODNR 1954-83; Terran 1993).

Most other residents within a 4-mile radius of the Systech site are served by the Warren County or Middletown municipal water systems. Except for those residents on the outskirts of Franklin previously discussed, these systems currently obtain water from wellfields more than 4 miles away from the Systech site (City of Middletown 1993; PRC 1994c). Warren County is developing a new wellfield about 1.5 miles west of the Systech site, near Twin Creek, southwest of Carlisle, on land owned by MCD. The new wellfield will draw water from the buried valley aquifer and will serve about 9,000 Warren County residents currently served by other Warren County wellfields located more than 4 miles away from the Systech site. Warren County does not plan to extend water service to Carlisle. The new wellfield is expected to be in use by summer 1995 (PRC 1993b; 1993c).

5.2 SURFACE WATER MIGRATION PATHWAY

The analytical results of soil and sediment samples collected during the ESI indicate that hazardous substances are present in soils at the Systech site and have possibly migrated into the drainage ditches surrounding the site. Some of these substances (such as benzo[b]fluoranthene) have relatively high toxicity values and human food chain bioaccumulation potential (U.S. EPA 1993). However, significant concentrations of hazardous substances were not detected in a sediment sample collected where the site drainage enters Clear Creek, and therefore detectable quantities of contaminants do not appear to be migrating into nearby surface water bodies.

All surface runoff from the site drains to Clear Creek, either directly, or by way of the drainage ditches around the site perimeter, which flow intermittently (PRC 1993b). The total drainage area for the site is about 2 acres (PRC 1993b; Terran 1993). The maximum 2-year, 24-hour rainfall for the area is about 2.75 inches (NOAA 1992). The site is located within the 100-year floodplain of the Great Miami River (FEMA 1987). The distance from the nearest documented point of contamination (soil sample location SD-3) to Clear Creek is about 50 feet. These factors indicate a relatively high potential for contaminants to migrate from the Systech site to Clear Creek.

Clear Creek is a small to moderate-sized perennial stream in the site vicinity, with an estimated average flow in the range of about 50 to 100 cubic feet per second (cfs) (PRC 1993b). Clear Creek is used for fishing in the site vicinity (PRC 1992b). No other use of Clear Creek has been documented. Clear Creek flows into the Great Miami River about 0.5 mile west of the Systech site. The flow rate in the Great Miami River, which is also used for fishing, ranges from about 300 to 500 cfs in the area (USGS 1968). Fishing activity in these streams appears to be predominantly recreational; therefore, the amount of fish consumed is probably minimal. However, PRC assumed that fish consumption does occur. No drinking water intakes, endangered species habitats, or wetlands have been identified within 15 miles downstream of the Systech site (PRC 1992b; 1993b).

5.3 SOIL EXPOSURE PATHWAY

Several TCL compounds were detected in soil samples collected at the Systech site during the ESI. However, the amount of contaminated soil at the site is assumed to be relatively small, because much

of the site is paved or covered by concrete structures. PRC estimated the total size of the unpaved areas potentially containing contaminated soil at about 1.5 acres.

There are no workers or residents at the Systech site. The total population residing within a 1-mile radius of the site is about 3,287 people (Frost Associates 1994). However, nearby residents are unlikely to come into contact with contaminated soil, due to limited access. The site is surrounded by a chain-link fence topped with barbed wire. The site does not appear to be used by local children for recreational purposes. During the reconnaissance, PRC observed some graffiti on the wall inside the former pump house, indicating some unauthorized access; however, PRC saw no evidence of frequent recreational use (PRC 1993b).

5.4 AIR MIGRATION PATHWAY

Although nearby residents complained of odors from the Systech site during the late 1970s, no sources likely to release contaminants to air remain on site. Also, it does not appear that analysis of air samples, documenting the source and characteristics of the airborne contaminants, was performed when the odors were reported. The only potential sources of airborne contamination remaining at the Systech site are surficial soils, which were found to contain benzo(b)fluoroanthene, pyrene, and several other TCL compounds at locations sampled during the ESI.

About 97,653 people reside within a 4-mile radius of the Systech site (Frost Associates 1994). No sensitive environments have been identified in this area. In general, the site's potential to release significant quantities of airborne contaminants appears to be limited, because much of the site is paved and the unpaved areas are generally well vegetated. During sampling activities, PRC performed ambient air monitoring with a photoionization detector; no readings above background were noted (PRC 1993b).

POTENTIAL HAZARDOUS WASTE SITE
SITE INSPECTION REPORT
PART 3 - DESCRIPTION OF HAZARDOUS CONDITIONS AND INCIDENTS

I. IDENTIFICATION

01 STATE	02 SITE NUMBER
OH	D 030 935 862

II. HAZARDOUS CONDITIONS AND INCIDENTS

01 ■ A. GROUNDWATER CONTAMINATION — 02 ■ OBSERVED (DATE: June 1993) — ☐ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: 26,864 — 04 NARRATIVE DESCRIPTION

Chloroethane, ethylbenzene, xylenes, and arsenic were detected in on-site groundwater samples during the 1993 ESI. Solvents, including 1,1,1-trichloroethane, were also detected in groundwater samples during a 1987 SSI. No drinking water wells are suspected to be subject to actual contamination.

01 ☐ B. SURFACE WATER CONTAMINATION — 02 ☐ OBSERVED (DATE:) — ■ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: N/A — 04 NARRATIVE DESCRIPTION

During the ESI contaminants (polynuclear aromatic hydrocarbons [PAHs] have been detected in drainage ditch soils adjacent to site. The ditches drain into Clear Creek. However, no contaminants were detected in sediments in Clear Creek.

01 ☐ C. CONTAMINATION OF AIR — 02 ☐ OBSERVED (DATE:) — ☐ POTENTIAL — ■ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: Unknown — 04 NARRATIVE DESCRIPTION

Nearby residents complained of odors on several occasions in 1970s. However, no wastes remain on site and there have been no complaints since Systech closed in 1978. No sampling was performed in 1978 to document the nature of airborne contamination.

01 ☐ D. FIRE/EXPLOSIVE CONDITIONS — 02 ☐ OBSERVED (DATE:) — ☐ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: — 04 NARRATIVE DESCRIPTION

N/A. No waste inventory remains on site.

01 ☐ E. DIRECT CONTACT — 02 ☐ OBSERVED (DATE:) — ☐ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: — 04 NARRATIVE DESCRIPTION

Minimal potential; all waste inventory removed: areas of potentially-contaminated soils are fenced.

01 ■ F. CONTAMINATION OF SOIL — 02 ■ OBSERVED (DATE: June 1993) — ☐ POTENTIAL — ☐ ALLEGED
03 AREA POTENTIALLY AFFECTED: Max. of 1.5 (Acres) — 04 NARRATIVE DESCRIPTION

Several organic contaminants (PAHs) were detected in on-site soil samples collected during the ESI.

01 ■ G. DRINKING WATER CONTAMINATION — 02 ☐ OBSERVED (DATE:) — ■ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: 26,864 — 04 NARRATIVE DESCRIPTION

Several municipalities and numerous private residences use groundwater in the area. Contaminants have been detected in groundwater at the Systech site but are not suspected to be present in any drinking water supply wells.

01 ■ H. WORKER EXPOSURE/INJURY — 02 ■ OBSERVED (DATE: 1976) — ☐ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: 2 — 04 NARRATIVE DESCRIPTION

Two workers died of cyanide poisoning while cleaning an aboveground tank in 1976.

01 ☐ I. POPULATION EXPOSURE/INJURY — 02 ☐ OBSERVED (DATE:) — ☐ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: N/A — 04 NARRATIVE DESCRIPTION

Minimal potential - site access is restricted by fence. No waste inventory remains on site.

EPA

POTENTIAL HAZARDOUS WASTE SITE
SITE INSPECTION REPORT
PART 3 - DESCRIPTION OF HAZARDOUS CONDITIONS AND INCIDENTS

I. IDENTIFICATION

01 STATE	02 SITE NUMBER
OH	D 030 936 862

II. HAZARDOUS CONDITIONS AND INCIDENTS *(Continued)*

01 ☐ J. DAMAGE TO FLORA — 02 ☐ OBSERVED (DATE: _____) — ☐ POTENTIAL — ☐ ALLEGED
04 NARRATIVE DESCRIPTION

None known.

01 ☐ K. DAMAGE TO FAUNA — 02 ☐ OBSERVED (DATE: _____) — ☐ POTENTIAL — ☐ ALLEGED
04 NARRATIVE DESCRIPTION *(Include name(s) of species)*

None known.

01 ☐ L. CONTAMINATION OF FOOD CHAIN — 02 ☐ OBSERVED (DATE: _____) — ■ POTENTIAL — ☐ ALLEGED
04 NARRATIVE DESCRIPTION

Contaminants detected in ditch soils could migrate to Clear Creek and Great Miami River.

01 ☐ M. UNSTABLE CONTAINMENT OF WASTES *(Spills/Runoff/Standing liquids, Leaking Drums)* — 02 ☐ OBSERVED (DATE: _____) — ☐ POTENTIAL — ☐ ALLEGED
03 POPULATION POTENTIALLY AFFECTED: N/A — 04 NARRATIVE DESCRIPTION

No wastes remain on site. All site runoff flows to ditches or Clear Creek. Minimal potential for soil contaminants to migrate off site.

01 ☐ N. DAMAGE TO OFFSITE PROPERTY — 02 ☐ OBSERVED (DATE: _____) — ☐ POTENTIAL — ☐ ALLEGED
04 NARRATIVE DESCRIPTION

None suspected. See item 11.M above.

01 ☐ O. CONTAMINATION OF SEWERS, STORM DRAINS, WWTPs — 02 ☐ OBSERVED (DATE: _____) — ■ POTENTIAL — ☐ ALLEGED
04 NARRATIVE DESCRIPTION

Wastes pre-treated on-site from 1974 to 1978 were subsequently treated at MCD's Franklin WWTP - no other information is available.

01 ☐ P. ILLEGAL/UNAUTHORIZED DUMPING — 02 ☐ OBSERVED (DATE: _____) — ☐ POTENTIAL — ☐ ALLEGED
04 NARRATIVE DESCRIPTION

None known. Several spills were reported to OEPA; however, no intentional on-site disposal (authorized or unauthorized) is suspected.

05 DESCRIPTION OF ANY OTHER KNOWN, POTENTIAL, OR ALLEGED HAZARDS

None known.

III. TOTAL POPULATION POTENTIALLY AFFECTED: 26,864

IV. COMMENTS

Solvents in site groundwater possibly related to solvent recovery operation that was on site in late 1970s. Source of arsenic in site groundwater is unconfirmed at this time.

03 NUMBER OF BUILDINGS WITHIN TWO (2) MILES OF SITE	04 DISTANCE TO NEAREST OFF-SITE BUILDING
Unknown	0.1 (mi)

05 POPULATION WITHIN VICINITY OF SITE (Provide narrative description of nature of population within vicinity of site, e.g., rural, village, densely populated urban area)

The site is on the southwest edge of Franklin, Ohio. Relatively densely populated areas are east and south of the site; the areas to the west and north are open/rural land. Some heavy industry is located in the area around the site.

14 DESCRIPTION OF SITE IN RELATION TO SURROUNDING TOPOGRAPHY

The site is located near the south edge of the Great Miami River Valley. The valley wall is about 600 feet south of the site. The site is located on a relatively flat terrace, with a slight slope toward Clear Creek (north). The site is surrounded by ditches; therefore no run-on from off-site areas occurs. Site runoff drains to Clear Creek.

02 DESCRIPTION OF FEDERAL, STATE, LOCAL REGULATORY/ENFORCEMENT ACTION

The Warren County Health Department Southwest Ohio Air Pollution Control Agency, investigated citizens' complaints regarding odors at the site in 1978. The odors were suspected to be related to either an on-site solvent recovery operation, or a spill of solvents into a diked area around two tanks.

The matter was subsequently investigated by Ohio EPA. The odor problem, and groundwater contamination discovered in 1977, resulted in closure of the site in 1978.

CRQL = Contract–required quantitation limit

CRDL = Contract–required detection limit

N/A = Not applicable

-- = Not analyzed

TABLE D-1 (Continued)
SUMMARY OF MONITORING WELL (GROUNDWATER) SAMPLE ANALYSES

SYSTECH

GENERAL QUALIFIERS	DEFINITION
U	The compound or analyte was analyzed for, but not detected. Associated value is the sample quantitation limit (SQL).
H	Analytical bias is high.
L	Analytical bias is low.
?	Analytical bias is unknown.
J	Value is estimated (also indicates a compound that is detected below the CRQL).
COMPOUND QUALIFIERS	**DEFINITION**
P	Variance between GC columns was greater than 25 percent in pesticide or Aroclor (PCB) analyses. The lower value is reported.
B	Compound was detected in an associated laboratory blank.
D	Compound was identified at a secondary dilution factor.
ANALYTE QUALIFIERS	**DEFINITION**
B	Value is below the CRDL.
N	Matrix spike percent recovery values were outside of control limits.
W	Furnace AA post-digestion spike recovery values were outside of control limits.
*	Duplicate relative percent difference values were outside of control limits.
S	Analyte concentration was determined by Method of Standard Additions (MSA).
+	Correlation coefficient for MSA was less than 0.995.

Notes:

All concentrations are in micrograms per kilogram (µg/kg) unless otherwise noted.

CRQL = Contract-required quantitation limit

CRDL = Contract-required detection limit

N/A = Not applicable

(a) = Samples SD-3, SD-4 and SD-5 were originally collected as sediment samples but were redesignated as soil samples due to the absence of surface water at the sample locations.

TABLE D-3 (Continued)

SYSTECH

SUMMARY OF SOIL SAMPLE ANALYSES

GENERAL QUALIFIERS	DEFINITION
U	The compound or analyte was analyzed for but not detected. Associated value is the sample quantitation limit (SQL).
H	Analytical bias is high.
L	Analytical bias is low.
J	Value is estimated (also indicates a compound that is detected below the CRQL).
?	Analytical bias is unknown.
COMPOUND QUALIFIERS	**DEFINITION**
P	Variance between GC columns was greater than 25 percent in pesticide or Aroclor (PCB) analyses. The lower value is reported.
B	Compound was detected in an associated laboratory blank.
ANALYTE QUALIFIERS	**DEFINITION**
B	Value is below the CRDL.
E	Value is estimated due to matrix interferences.
N	Matrix spike percent recovery values were outside of control limits.
*	Duplicate relative percent difference values were outside of control limits.
